Rationale
First year rowing athletes have an increased risk for injuries, especially during high training load. Dietary protein may stimulate recovery and therefore may reduce the risk for injuries during extensive training periods. In this pilot, we studied the association between protein intake and the incidence of injuries in freshman rowing athletes during competitive season.

Methods
Freshman rowers (n=22) were included from four boats: 2 coxed eights (8+), 1 coxed four (4+) and 1 coxed quad (4x+). Clarson1 injury questionnaire and 3-day food record were performed at start and after 8 weeks of competition. Correlation between protein intake and injury incidence was analyzed with chi-squared test.

Results
Data analysis was completed for 22 freshman rowers (mean age 21 ± 2 years). In total, 64% (14/22) of the athletes reported an injury and in total 20 injuries were reported. Next to this reported injuries 27% (6/22) of the athletes had to interrupt rowing because of the injury (mainly airway/flue).

Table 1. Dietary protein consumption injured vs non-injured

Conclusion
Competitive freshmen rowers are prone to injuries during the competition season. Adequate dietary protein intake may be associated with lower incidence of injuries in freshman rowers. Further research needs to be conducted to investigate the role of protein intake on injuries in freshman rowers or other sports with related high training loads.
