## Introduction

As part of the BrightSky project in the journey towards Schiphol's ambitious sustainability goals to achieve an emissions-free airport by 2030 and an autonomous airside by 2050, the emissions emitted by ground support equipment (GSE) were identified, to assess their impact on air quality and health. This investigation focuses on personnel close to the source and directly exposed to the emissions.

Emissions → Dispersion → Concentrations → Impacts

The pathway from aviation emissions is complex, generating important impacts on local and regional air quality and public health through dispersion processes.

## Methodology

(1) Identification of pollutants from GSE and effect to health

- Carbon monoxide (CO)
- Nitrogen oxides (NO<sub>x</sub>)
- Sulphur dioxide (SO<sub>2</sub>)
- Particulate matter (PM<sub>2.5</sub> & PM<sub>10</sub>)
- Volatile organic compounds (VOC)
- Ozone (O<sub>3</sub>)

(2) Identification of other emissions

- Carbon dioxide (CO<sub>2</sub>)
- Noise

(3) Calculation of total emission using emission factors:

$$E = A * EF$$

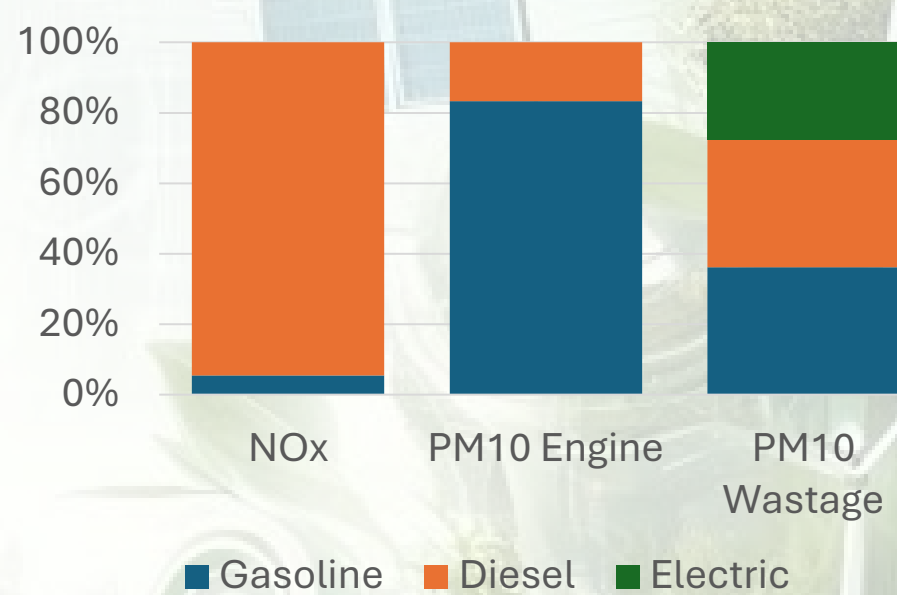

Where:

- E is the emission
- A is the activity rate (fuel consumption)
- EF is the emission factor

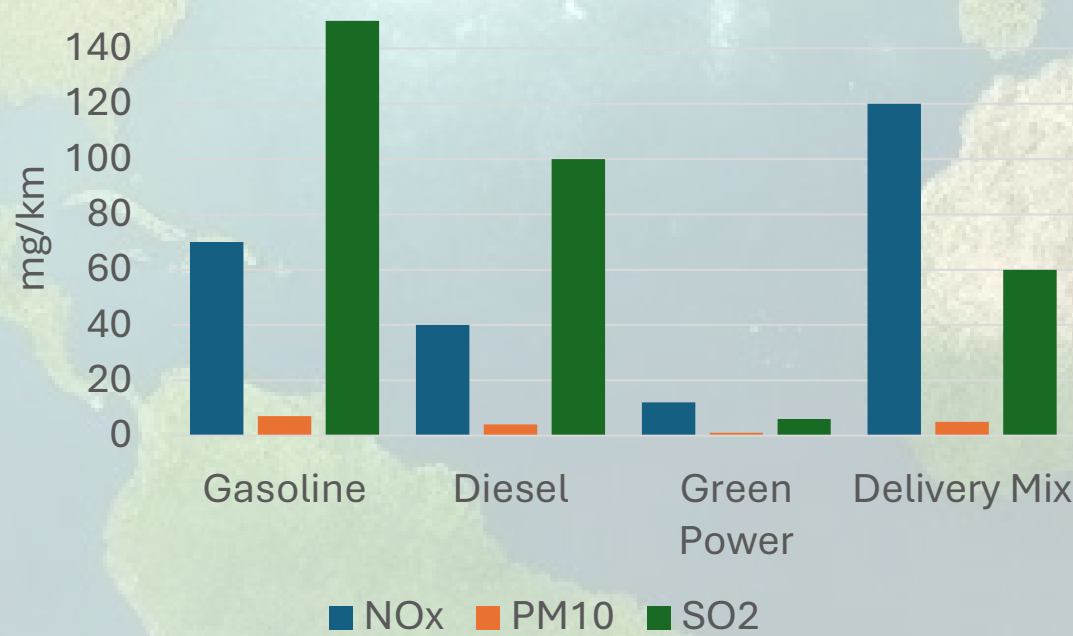

Pollutant	Affected body parts
Carbon monoxide (CO)	Brain, blood, heart & nervous system
Nitrogen oxides (NO <sub>x</sub> )	Lungs & airways
Sulphur dioxide (SO <sub>2</sub> )	Lungs, airways & heart
Particulate matter (PM <sub>2.5</sub> & PM <sub>10</sub> )	Lungs, heart & bloodstream
Volatile organic compounds (VOC)	Lungs & airways
Ozone (O <sub>3</sub> )	Lungs & airways

## Results

Emission Comparison for Gasoline, Diesel, and Electric Vehicles

Fuel and Electricity Emissions for Gasoline, Diesel, and Electric Vehicles

Comparison of Health Risks for Current, 2030, and 2050 at Schiphol Airport

• Diesel vehicles emit the highest levels of NO<sub>x</sub> and PM<sub>10</sub> compared to gasoline and electric vehicles.

• Electric vehicles have zero emissions from the engine and minimal PM<sub>10</sub> wastage, making them the cleanest option.

- Gasoline and diesel fuel production emit significant levels of NO<sub>x</sub>, PM<sub>10</sub>, and SO<sub>2</sub>.
- Green power shows the lowest emissions, highlighting the importance of renewable energy sources.
- The delivery mix, a combination of energy sources, still shows notable emissions, particularly NO<sub>x</sub>.

- Transitioning to electric (EV) by 2030 and autonomous vehicles (AV) by 2050 significantly reduces overall health risks (SO<sub>2</sub>, PM<sub>10</sub>, and NO<sub>x</sub> risks compared to diesel vehicles.
- The current diesel situation poses high health risks, while both future scenarios show substantial improvements in reducing these risks.

## Conclusion

Vehicle electrification and autonomous operations minimize the number of workers operating in the apron area. This transition to electric (EV) vehicles by 2030 and autonomous vehicles (AV) by 2050 significantly reduces overall health risks in personnel, associated with SO<sub>2</sub>, PM<sub>10</sub>, and NO<sub>x</sub> emissions, compared to the diesel situation in 2024.
